ABSTRACT

This study aimed to investigate the correlation between progesterone hormone concentration and number of fetus as well as the difference in progesterone hormone concentration from different gestation periods in Etawa crossbred (EC). Five EC goats used in this study were injected with 2 mL of 5.5 mg prostaglandin F2 α (PGF2 α , Capriglandin) intramuscularly, with an interval of 10 days. Goats that showed symptoms of estrus were mated naturally with male goats. Blood samples were taken on the 7th, 14th, 21st, and 75th days of gestation. Progesterone hormone concentration was determined using enzyme linked immunosorbent assay (ELISA). The number of fetus was determined at 35th gestational day using ultrasonography (USG). Four out of 5 goats were found to have 1 fetus and 1 goat had 2 fetuses. The progesterone concentration on the 7th, 14th, 21st, and 75th days of gestation in goats with single fetus were 5.21, 7.78, 11.97, and 18.78 ng/mL, respectively, while in goat with two fetuses were 8.44, 14.53, 16.81, and 22.73 ng/mL, respectively. The correlation (r) between progesterone hormone concentration and number of fetus on the 7th, 14th, 21st, and 75th days of gestation were 0.442, 0.854, 0.592, and 0.757, respectively. It is concluded that progesterone concentrations are highly correlated to the number of fetus in each gestation period in EC goats.

Key words: EC goats, ELISA, number of fetuses, progesterone

ABSTRAK

Penelitian ini bertujuan mengetahui hubungan konsentrasi hormon progesteron dengan jumlah fetus dan mengetahui perbedaan konsentrasi hormon progesteron pada periode kebuntingan yang berbeda. Penelitian ini menggunakan 5 ekor kambing peranakan Etawa (PE). Seluruh kambing diinjeksi dengan 5,5 mg prostaglandin F2 α (PGF2 α , Capriglandin) secara intramuskulus, 2 kali injeksi dengan interval 10 hari. Kambing yang menunjukkan gejala estrus dikawinkan secara alami dengan pejantan. Sampel darah diambil pada hari kebuntingan ke-7, 14, 21, dan 75. Pengukuran konsentrasi progesteron dilakukan dengan metode enzyme linked immunosorbent assay (ELISA). Penentuan jumlah fetus dilakukan pada usia kebuntingan 35 hari menggunakan ultrasonografi (USG). Dari 5 ekor kambing yang digunakan, diketahui 4 ekor mempunyai anak tunggal dan 1 ekor mempunyai anak dua. Hasil penelitian menunjukkan bahwa konsentrasi hormon progesteron pada hari kebuntingan ke-7, 14, 21, dan 75 masing-masing adalah 5,21; 7,78; 11,97; 18,78 ng/ml pada kambing dengan jumlah fetus satu dan 8,44; 14,53; 16,81 dan 22,73 ng/ml pada kambing dengan jumlah fetus dua. Hubungan (r) konsentrasi hormon progesteron dengan jumlah fetus kambing peranakan Etawa pada hari ke-7, 14, 21, dan 75 kebuntingan masing-masing adalah 0,442; 0,854; 0,592; dan 0,757. Disimpulkan bahwa konsentrasi hormon progesteron mempunyai korelasi sangat kuat dengan jumlah anak pada kambing PE.

Kata kunci: kambing PE, ELISA, jumlah fetus, progesteron

INTRODUCTION

Gestation is an important way for female mammals to preserve the offspring of a species. Gestation is started from the fusion of spermatozoa and ovum into a new cell called zygote. Gestational period is the span of time extending from fertilization or conception until parturition. The duration of gestation in goats is 148-154 (Hafez, 2000). According to Feradis (2010), the normal duration of gestation among lambs and goats is about 149 days. Goats have some advantageous traits such as fast breeding; they often give birth to more than 1 (2-4) goat and in tropical regions goats could give birth 3 times in 2 years (Sindoeredjo, 1996).

To maintain a normal gestation, hormones are required in an appropriate proportion. The formation of placenta and fetal endocrine glands create a hormonal interaction between the mother and the fetus. The

hormones essential to maintain gestation are ovarian progesterone and estrogen, as well as gonadotropin and prolactin secreted by adenohypophysis (Feradis, 2010).

Progesterone is one of the important reproduction-related hormones secreted by cells inside luteal corpus luteum (Hafez, 2000). Progesterone is important to prepare uterine environment for implantation and the increase in its concentration during gestation is important to maintain gestation (Dunlap and Stomshak, 2004). According to Feradis (2010), progesterone is important for blastocyst survival before implantation and to maintain gestation by creating an endometrial environment suitable for embryo survival and growth, and also to slow spontaneous uterine motility and reduce myometrium sensitivity towards oxytocin.

Progesterone concentration is proportionally correlated to the number of corpus luteum formed in

the ovaries (Tjptosumirat, 2009). Siregar (2002) reported that among lambs, progesterone concentration correlate to the number of corpus luteum during corpus luteum formation, while during gestation it is correlated to the number of fetus. Chauhan and Waziri (1991) reported that for fetal number estimation, serum progesterone concentration was significantly higher among lambs with 2 and 3 fetuses compared to single fetus with the values of 19.2, 29.9, and 9.2 ng/mL, respectively. Manalu *et al.* (1996) reported that progesterone hormone concentration during the last two months of gestation among goats with 2 fetuses was higher than goats with single fetus, 11.11 and 5.79 ng/mL, respectively. Therefore, a study is needed to investigate the correlation between progesterone hormone concentration and number of fetuses of Etawa crossbred (EC) goats in different periods of gestation.

MATERIALS AND METHODS

The samples used in this study were five female EC goats that have met clinical healthy criteria, had a history of gestation, gave birth to 1 and 2 kids from the last gestation and aged 2-4 years old. All female goats were injected twice with 5.5 mg prostaglandin F2 α (PGF2 α , Capriglandin) intramuscularly, with an interval of 10 days. Estrus observation was done directly and assisted by male goats every day after the second injection. Estrus observation was done three times a day visually and assisted by male goats at 08.00, 12.00, and 16.00 (GMT +7). The symptoms observed were swelling and redness of the vulva, excessive urination, behavioral change, discharge of transparent liquid from vulva, and standing heat. Goats showing estrus symptoms were then mated naturally.

Goat blood samples were taken on the 7th, 14th, 21st, and 75th days of gestation. Blood used for hormonal assay was taken from jugular vein using 5 mL disposable syringe. The blood was then inserted into vacuum container and then placed inside ice thermos. The blood was transported to Reproduction Laboratory and centrifuged for 15 minutes at 2500 rpm for serum collection. The serum was collected using micropipette and inserted into microtube. Progesterone concentration was measured using enzyme-linked immunosorbent assay (ELISA) method.

The number of fetus was determined using ultrasonography (USG) in which the fetus, uterus, and placenta appeared white (*hyperechogenic/hyperechoic*) or gray (*isoechogenic/hypoechoic*), while the amnion and uterine lumen appeared as black (*hypoechogenic/anechoic*). The number of fetus was determined at the 35th day of gestation age based on the observation of embryonic sac, amniotic fluid, fetus, and fetal heart.

Data Analysis

The correlation between progesterone hormone concentration and the number of goat fetus was analyzed using simple regression and correlation.

RESULT AND DISCUSSION

The image of USG showed that four of the five EC goats had single fetus while 1 EC goat had 2 fetuses. The progesterone hormone concentration of the EC goats is shown in Figure 1.

Figure 1. Progesterone hormone concentration (ng/mL) at different gestation days

Figure 1 showed that progesterone hormone concentration on the 7th, 14th, 21st, and 75th days of gestation in goat with single fetus were 5.21, 7.78, 11.97, and 18.78 ng/mL, respectively, while in goat with 2 fetuses were 8.44, 14.53, 16.81, and 22.73 ng/mL in goat, respectively. Figure 1 also showed that progesterone hormone concentration of EC goats with single fetus was lower compared to those with two fetuses. Budiarsana and Sutarna (2001) also reported a similar result, whereby EC goats with single fetus had a lower progesterone hormone concentration compared to EC goats with multiple fetuses.

The average progesterone concentration on the 7th day of gestation in EC goats with 2 fetuses was twofold higher compared to single fetus (8.44 and 5.21 ng/mL, respectively). This is because the progesterone concentration during formation of corpus luteum is correlated to the number of corpus luteum in the ovaries, as reported previously by Tjptosumirat (2009) and Manalu and Sumaryadi (1995). Moreover, Jarell and Dziuk (1991) observed that after gestation, the number of fetus and the number of corpus luteum significantly influence progesterone level. In goat, Selvaraju *et al.* (2007) found that the increasing of corpus luteum number from 0, 1, 2, 3, and >3 resulted in the increasing of progesterone concentration from 0.0 ± 0.0 , 3.21 ± 0.13 , 4.21 ± 0.36 , and 5.17 ± 1.15 ng/mL, respectively.

The result of simple regression and correlation analysis showed that the correlation (*r*) between progesterone hormone concentration and the number of fetus on the 7th, 14th, 21st, and 75th days of gestation were 0.442 (medium correlation), 0.854 (very strong correlation), 0.592 (medium correlation), and 0.757 (strong correlation), respectively (Figure 2). In line with this study, Adriani *et al.* (2007) reported that the correlation between progesterone and the number of corpus luteum was strong (*r* = 0.74).

Determinant coefficient (R²) showed that 72.9% of the variation in the number of fetus can be explained by the variation in progesterone hormone concentration while the remainder is influenced by other variables. Based on regression coefficient, the regression equation obtained is $Y = 0.214 + 0.108X$. The value of 0.108 means that every 1 ng/mL increases in progesterone concentration in EC goats would increase the number of fetus by 0.108. Hence, the higher the progesterone concentration, the higher the number of goat fetus produced.

Figure 2. Scatter plot of the correlation between progesterone hormone concentration and the number of Etawa crossbred goat fetus on the 7th, 14th, 21st, and 75th days of gestation

The correlation was only medium on the 7th day of gestation because corpus luteum had just started to secrete progesterone hormone. Arinbawa *et al.* (2012) stated that the increase in progesterone level is correlated to the development of corpus luteum during estrus cycle. Corpus luteum started to function on the 1st day after estrus, indicating that luteinization had started after ovulation, during progesterone hormone is produced. Llewelyn *et al.* (1995) also stated that the increase in progesterone level is accounted by the production of progesterone by corpus luteum at the initial of gestation which then continues to increase during luteal phase.

Progesterone level continues to increase until the 14th and 21st day of gestation. On the 14th day, progesterone hormone concentration in goats with single fetus vs 2 fetuses was 7.78 vs 14.53 ng/mL while on the 21st day was 11.97 vs 16.81 ng/mL. Budiarsana and Utama (2001) reported that the increase in progesterone level occurred in the first 2-3 weeks after mating. Jarell and Dziuk (1991) also reported a similar result wherein the increase in progesterone level has occurred since the beginning of gestation until the 13th day of gestation, at which point the level starts to decrease. This decrease is caused by the shrinkage of corpus luteum at day 12-14; hence if the ovum was not fertilized, the production of progesterone would eventually decrease (Hafez, 2000).

The average progesterone hormone concentration on the 75th day of gestation in EC goat with two fetuses was higher compared to single fetus (18.78 vs 22.73 ng/mL) which was in line with previous observation by Adriani *et al.* (2007). The average of progesterone

hormone concentration in EC goats during 21 weeks of gestation in this study was 8.56 ± 3.13 for single fetus and 10.73 ± 3.50 for two fetuses. All the above observations indicated that progesterone hormone concentration was correlated with the number of fetus. Similarly, Siregar (2002) also proved that progesterone concentration in mid-gestation is correlated to the number of fetus.

CONCLUSION

Based on the result, it is concluded that progesterone concentration is highly correlated to the number of fetus in each gestation period in EC goats.
